

# Seed-level internal and external validation: effect of proxy-integrated training

All summaries use 10 seeds; external comparisons use an identical 11-peptide set

## A Internal discrimination (MCC)

Dots = individual seeds; large points and bars = mean and 95% CI

## B External positive detection

Calculated on the same 11 external positives in both conditions

## C Generalization gap

External detection minus internal recall; zero indicates agreement

## D Proxy-induced change

Upper-right = improvement in internal MCC and external detection
